## Abstract

Many recent studies on large-scale language models have reported successful in-context few-shot learning ability. However, the in-depth analysis of when in-context learning occurs is still lacking. For example, it is unknown how in-context learning performance changes as the training corpus varies. Here, we investigate the effect of the source and size of the pretraining corpus in a Korean GPT-3. From our in-depth investigation, we introduce the following observations: (1) in-context learning performance heavily depends on the corpus domain source, and the size of pretraining corpus does not necessarily predict the emergence of in-context learning, (2) in-context learning ability can emerge when a language model is trained on a combination of multiple corpora, even when each corpus does not result in in-context learning on its own, (3) pretraining with a corpus related to a downstream task does not always guarantee the competitive in-context learning performance of the downstream task, and (4) the relationship between language modeling (measured in perplexity) and in-context learning does not always correlate: e.g., low perplexity does not always imply high in-context learning performance.

## 1 Introduction

NLP community has surprised that zero/few-shot in-context learning ability emerges in a large-scale language model such as GPT-3 (Brown et al., 2020) despite no duplication between downstream task data and the pretraining corpus. Indeed, in-context learning uses a natural language description and a few examples to prime a language model. Then the language model can predict the answer of a new example without updating the language model’s parameters. Since the release of GPT-3, various large-scale in-context language models have been proposed, including GPT-neo (Black et al., 2021),

HyperCLOVA (Kim et al., 2021), and Pangu- $\alpha$  (Zeng et al., 2021).

There still remain many questions on language models’ in-context learning capability despite these successful reports. For example, the relationship between the choice of a pretraining corpus and downstream in-context learning task accuracy is unknown. Previous studies argue pretraining with the corpus similar to the downstream task improves the downstream performance, but these observations are often limited to the case where a pretrained language model is finetuned for the downstream task (Gururangan et al., 2020; Lee et al., 2020; Micheli et al., 2020).

In addition, analysis on the relation between the validation perplexity of a language model and in-context learning performance is still less investigated. While previous research on in-context learning implicitly assumes that perplexity is predictive of in-context learning performance, by showing scaling law property of their model (Kaplan et al., 2020; Brown et al., 2020; Kim et al., 2021), their explicit correlations are less discovered.

Motivated by this lack of in-depth analysis on the relationship between in-context learning and corpus properties, we vary the sources and sizes of pretraining corpora and analyze their impact on in-context learning, using a Korean GPT-3 (Kim et al., 2021). We use HyperCLOVA corpus, which is a large-scale pretraining corpus mainly in Korean collected by Kim et al. (2021), as a base corpus from which we derive pretraining corpora for our experiments. Our major findings include:

- **Corpus Source:** The in-context learning performance depends heavily on corpus sources, and with some sources, in-context learning does not work effectively. For example, the model trained only on `Blog` corpus achieves competitive in-context learning performance, but training on `Cafe` or `News` corpus hardly yields in-context learning ability.

\* Equal contribution.

- **Corpus Combination:** In-context learning ability can emerge by fusing two corpora, even when each on its own does not result in in-context learning. For example, while training only on `KiN` corpus, which consists of QnA websites, or `Ency` corpus, which consists of Encyclopedia websites, in-context learning ability was not observed, but training on both corpora makes the emergence of in-context learning.
- **Domain Relevance:** Pretraining with a corpus related to a downstream task is not indicative of the competitive in-context learning performance. For example, training on only `News` corpus does not even yield in-context learning ability on a News-related downstream task, e.g., news topic classification based on its title, KLUE-YNAT (Park et al., 2021).
- **Perplexity:** Although perplexity and in-context learning accuracies correlate well when training a single model, perplexity alone does not reflect the difference in in-context learning accuracies across different language models, particularly when they were trained using different pretraining corpora. For example, `Cafe` model, the model trained with `Cafe` corpus, has the second lowest validation perplexity on various domain sources after `Blog` model, but fails to emerge in-context learning.

## 2 Related Work

### 2.1 In-context Learning

Brown et al. (2020) demonstrate the concept of in-context learning, where a few training examples and/or task descriptions are provided together with a new input to a large-scale LM for it to produce a target of this input, without requiring any parameter update. Since then, a few follow-up studies have tried to improve the in-context learning ability (Zhao et al., 2021; Holtzman et al., 2021). Compared to a more conventional approach based on finetuning, such an attempt with in-context learning has a benefit of reduced cost in AI production, as discussed by Bommasani et al. (2021); Kim et al. (2021).

### 2.2 Domain Relevance on Pretraining Corpus

Previous studies argue a better downstream accuracy is observed with a pretraining corpus more

similar to the downstream task corpus (Gururangan et al., 2020; Lee et al., 2020; Micheli et al., 2020). For example, Gururangan et al. (2020) conduct an intensive study and show that further pretraining with the corpus related to the downstream task results in higher downstream task performance. However, these observations are limited to the case where a pretrained language model is finetuned for the downstream task.

There are a few studies on the relationship between effects of different corpus on the relationship between pretraining and in-context learning. A notable example is Codex, where GPT-3 is trained on Github corpus so that the model can generate code from comments (Chen et al., 2021a). However, the corpus used for Codex is limited to code comments and the corresponding code. We study the effect of pretraining corpus on in-context learning performance using various domains.

### 2.3 Quantity and Quality of Pretraining Corpus

There have been several studies on the quantity and quality of pretraining data. Raffel et al. (2020) conduct an ablation study on different pretraining corpus on T5, and their filtered C4 corpus makes T5 perform better in downstream tasks. As with GPT-3, researchers generally improve the quality of their language model through data filtering (Brown et al., 2020; Kim et al., 2021). Our research differs from the existing work in that we focus on an in-depth analysis of how the amount of data and the corpus source affect in-context learning.

### 2.4 Multi-task Learning

Multi-task learning or meta-learning approaches, which explicitly finetune on the in-context learning objective by using numerous NLP tasks, are proposed recently to tackle zero/few-shot transfer to the unseen task at test time (Wei et al., 2021; Sanh et al., 2021; Chen et al., 2021b; Min et al., 2021). Unlike the studies in finetuning paradigm, many properties of the in-context learning related to pretraining corpus are still unknown.

## 3 Task Definition

### 3.1 Model

We use variants of Korean GPT-3 with different sizes and pretraining corpus. We mainly experiment with the models with 1.3B parameters, but we also include the result for 6.9B-sized models.

| Name     | Description                 | Tokens |
|----------|-----------------------------|--------|
| Blog     | Blog corpus                 | 273.6B |
| Cafe     | Online community corpus     | 83.3B  |
| News     | News corpus                 | 73.8B  |
| Comments | Crawled comments corpus     | 41.1B  |
| KiN      | Korean QnA website corpus   | 27.3B  |
| Modu     | Collection of five datasets | 6.0B   |
| Ency     | Encyclopedia corpus         | 1.7B   |
| Others   | Other corpus                | 55.0B  |
| Total    |                             | 561.8B |

Table 1: Descriptions of HyperCLOVA corpus (Kim et al., 2021).

All models have a maximum sequence length of 2,048, and use the same vocabulary for all the experiments. We use the morpheme-aware byte-level BPE tokenizer trained with HyperCLOVA corpus (Kim et al., 2021) for all models. We train multiple models with different portions of HyperCLOVA corpus to investigate the effects of the source and size of corpus on in-context learning ability.

### 3.2 Pretraining with Different Corpus

We analyze the effect of seven subcorpora in the HyperCLOVA corpus: `Blog`, `Cafe`, `News`, `Comments`, `KiN`, `Modu`, and `Ency`. Table 1 summarizes characteristics of the subcorpora. `Blog`, `Cafe`, and `News` are taken from blog, community sites, and online news articles of a Korean web portal service, respectively. `Comments` is the comment threads related to the three subcorpora mentioned above. `KiN` comes from a Korean online community QnA service similar to Quora. `Ency` is a collection of encyclopedic texts including Korean Wikipedia. `Modu` consists of five public datasets constructed by National Institute of the Korean Language<sup>1</sup>, including 3.2B of news, 2.1B written language, 0.4B of spoken language, 0.2B of web corpus, and 0.02B tokens of messenger. `Others` was excluded to investigate the explicit effects of domain corpus sources on in-context learning because `Others` is the corpus where various subcorpora are taken from multiple heterogeneous sources. Table 7 and 8 in Appendix show example instances of seven pretraining corpus in Korean and English, respectively. `ALL` denotes the original HyperCLOVA corpus including `Others`.

For corpora with less than 150B tokens, We assign 99% of each corpus to the pretraining corpus and randomly extract 10,000 examples from the

remaining 1% to the validation corpus for measuring validation perplexity. For corpora with more than 150B tokens, we make the training corpora 150B tokens via random sampling and construct a validation set with 10,000 examples randomly sampled from the remaining part. As a result, the maximum training set size of each corpus is 150B tokens and the entire validation set contains 70,000 examples for seven domains.

### 3.3 Downstream Tasks

We evaluate in-context learning performance of each corpus-specific model on four Korean downstream tasks used in Kim et al. (2021): NSMC<sup>2</sup>, KorQuAD (Lim et al., 2019), AI Hub translation<sup>3</sup>, and YNAT (Park et al., 2021). NSMC is a binary sentiment classification dataset on movie review. KorQuAD is a machine reading comprehension dataset similar to SQuAD 1.0 (Rajpurkar et al., 2016). AI Hub translation dataset consists of Korean-English parallel sentences from news, government websites, legal documents, etc. YNAT is a topic classification problem with seven classes.

It is noticeable that three downstream tasks are closely related to the HyperCLOVA corpus. Passages to construct KorQuAD are taken from Korean Wikipedia, which is also a part of the `Ency`. YNAT is a topic classification task of news headlines, so the downstream task is deeply related to the `News` corpus. A significant portion of parallel sentences for AI Hub translation dataset also comes from news articles. `KiN` corpus is also related to the translation task. About 2.5% of QnA data in `KiN` include Korean questions on the English language, as a foreign language. These question-style passages often include Korean-English sentence pairs in the passage. Vocabulary overlap between downstream tasks and HyperCLOVA corpus is depicted in Figure 1.

### 3.4 Experimental Details

We try our best to make the same Hyperparameter of Kim et al. (2021), including global batch size, training step, maximum sequence length, learning rate, and so on. In our experiments, the models are trained for 72K steps with a global batch size of 1,024. We note that under this setting, the number of tokens that were actually used in pretraining is 150B. Therefore, we set the maximum size of

<sup>1</sup><https://corpus.korean.go.kr/>

<sup>2</sup><https://github.com/e9t/nsmc>

<sup>3</sup><https://aihub.or.kr/aidata/87>

training corpus to 150B as mentioned in Section 3.2.

In most experiments, validation perplexity decreases monotonically as training goes on. Thus, we use the checkpoint at 72K step. The only exception is the `Ency` model. The `Ency` model has a minimum validation loss at 12K steps, which is likely to be caused by overfitting to pretraining data due to a small size of the data. Therefore, we use early-stopping checkpoints at the 12K steps for the report.

For optimization, AdamW (Loshchilov and Hutter, 2019) with the learning rate of  $2.0e-4$  and cosine learning rate scheduling was used. We use mixed precision training. Models are trained on the Nvidia Superpod which consists of 1,024 A100 GPUs spread across 128 nodes. Using Superpod, it spend around 18 hours to train 1.3B model with 72K steps.

For classification tasks such as NSMC and YNAT, we use a rank classification approach (Wei et al., 2021), where we compare pre-defined outputs (“positive” and “negative”) and take the higher probability one. KorQuAD and AI Hub are free-form completion tasks, where we directly generate output tokens using greedy decoding.

The number of shots in the few-shot experiments is set to fit the maximum sequence length. As a result, 70, 4, 4, and 70 shots are used for NSMC, KorQuAD, AI Hub, and YNAT, respectively. Downstream tasks are performed 12, 1, 3, and 6 times with different random seeds for NSMC, KorQuAD, AI Hub, and YNAT, respectively. We report the average performance. Random seed influences the sampling of shots from training data and their order. The reason KorQuAD has only one random seed is described in Appendix C. These all experimental setting from the number of shots and number of random trials basically comes from the experimental setting of Kim et al. (2021). However, we change the number of trials of YNAT from 3 to 6, because we found standard derivation of YNAT is relatively high.

Tables 9, 11, 13, and 14 in Appendix C show the examples of the few-shot prompts of NSMC, KorQuAD, AI Hub, and YNAT, respectively. Tables 10, 12, and 15 in Appendix C present the translated version for NSMC, KorQuAD, and YNAT.

Figure 1: Vocabulary overlap ratio between pretraining corpus and downstream task. Top 1,000 nouns are used to calculate the ratio. Nouns are extracted using in-house part-of-speech tagger.

### 3.5 Measuring Validation Perplexity

We report validation perplexity in various tables and figures to validate our argument. We use the term “PPL” to denote validation perplexities from the validation set. The validation set consists of 70,000 examples from seven corpus sources, as described in 3.2. We emphasize that, for calculating PPL, all experiments use **the same vocabulary and the same validation set**.

In Tables 2 and 3, we use *Italic* font for the results from a multi-domain model, which is pre-trained with two or more corpora. Since multi-domain model trains more domains than a single-domain model, the PPLs of multi-domain models are generally lower than those on single-domain models. To keep readers from directly comparing PPLs between a single-domain and a multi-domain models, we use italic font for the results from a multi-domain model.

## 4 Experimental Results

We perform intensive experiments to answer these main questions:

1. How large do the source and the size of pre-training corpora have effects on emerging in-context learning ability? (Section 4.1 and 4.2)
2. What is the effect of combining various corpora? (Section 4.3)
3. How large does domain relevance of corpus influence on model performances of the downstream task? (Section 4.4)

| Model          | Corpus Train | PPL    | NSMC (Acc)           | KorQuAD (EM) (F1) |              | AI Hub (BLEU) Ko→En En→Ko |                     | YNAT (F1)           |
|----------------|--------------|--------|----------------------|-------------------|--------------|---------------------------|---------------------|---------------------|
| Majority       | -            | -      | 50.35                | 0.0               | 0.0          | 0.0                       | 0.0                 | 8.26                |

| Comments 27B   | 27.0B        | 229.65 | <b>80.50</b> (1.44)  | <b>13.02</b>      | <b>31.53</b> | <b>1.70</b> (0.03)        | <b>3.28</b> (0.16)  | <b>25.79</b> (7.27) |

Table 2: In-context few-shot learning performance with different pretraining corpus. Models with 1.3B parameters are used. Standard deviation exists in parentheses. Majority means classifying each label with the primary class, and its score is 0 for KorQuAD and AI Hub. **Purple-underline** denotes the score is below the mean performance value of ALL and Majority baseline, and **Teal-bold** denotes the score is above. We use this mean value of Majority and ALL as the performance basis to prevent the in-context learning performance of each model from being distorted by the high basis performance of two classification tasks such as NSMC and YNAT.

- How strong is the correlation between validation perplexity and in-context learning of language models? (Section 4.5)

#### 4.1 Effect of Corpus Source

Table 2 shows the experimental results on various pretraining corpus sources.

It is noticeable that in-context learning ability emerges differently depending on pretraining corpus sources. For example, Blog model makes competitive in-context learning performance to ALL model, while each of Cafe and News models hardly shows in-context learning ability from Table 2. It is also noticeable that Modu model performs better than Cafe and News model although the size of Modu corpus is less than 1/10 of Cafe or News corpus, showing the corpus size is not the only factor to predict in-context learning performance. Likewise, it is also interesting that Cafe+News model also shows poor performance despite the same size to Blog and ALL, as shown in Table 3.

#### 4.2 Effect of Corpus Size

Table 4 shows the experimental results of ALL model on various pretraining corpus sizes. 56B and 6B correspond to the 1/10 and 1/100 of the original HyperCLOVA corpus with 560B tokens, respectively. The 56B tokens and 6B tokens models

are trained with around 3 and 25 epochs, respectively, so that both models can be trained with 72K training steps.

Results show that reducing the corpus size from 150B to 56B does not decrease the performance severely despite training with 1/10 of corpus. However, the performance degradation of 6B tokens model is remarkable comparing to ALL model. Nevertheless, it is noticeable that 6B tokens model still performs much better than Cafe+News model, which trains 150B tokens of Cafe and News corpus.

We can also see the case of three sizes of Blog corpus in Table 2. Blog and Blog 54B show achieves similar performance. However, like in ALL 6B, Blog 27B performs quite worse than Blog 54B.

Figure 3 shows the comparison between 1.3B-sized model and 6.9B-sized model. While a larger model presents better performance than a smaller model on KorQuAD and YNAT, there is no meaningful accuracy difference on NSMC.

#### 4.3 Effect of Combining Corpora

One of our main goals is to investigate the effects of combining multiple corpora from various sources on in-context learning performance. Table 3 includes the experiments on models trained from a corpus merged with multiple source corpora. The

| Corpus Type   | Corpus Train | PPL    | NSMC (Acc)  | KorQuAD (EM) (F1) |       | AI Hub (BLEU) Ko→En En→Ko |             | YNAT (F1)   |
|---|--------------|--------|-------------|-------------------|-------|---------------------------|-------------|-------------|
| ALL   | 150B         | 119.99 | 84.59(1.25) | 56.17             | 73.47 | 6.15(0.00)                | 23.36(0.00) | 59.57(4.30) |
| <b>The Case where In-context learning Emerges by Combining Two Poor Corpora</b>         |              |        |             |                   |       |                           |             |             |
| KiN+Ency  | 28.7B        | 164.69 | 59.17(9.34) | 42.09             | 61.00 | 8.99(0.31)                | 23.12(0.40) | 42.84(9.01) |
| Cafe+KiN  | 109.5B       | 141.92 | 76.42(4.68) | 38.45             | 59.00 | 8.41(0.68)                | 23.41(0.38) | 56.96(5.79) |
| <b>The Case where In-context learning Does Not Emerge by Combining Two Poor Corpora</b> |              |        |             |                   |       |                           |             |             |
| Cafe+News   | 150B         | 154.20 | 54.15(3.90) | 22.86             | 22.72 | 4.45(0.12)                | 17.77(2.19) | 8.19(5.32)  |

Table 3: In-context learning performance with different corpus combination. Purple-underline denotes the score is below the mean performance value of ALL and Majority baseline in Table 2, and **Teal-bold** denotes the score is above. 1.3B-size models are used.

| # of tokens | NSMC (Acc) | KorQuAD (EM) | AI Hub (BLEU) Ko→En En→Ko |       | YNAT (F1) |
|-------------|------------|--------------|---------------------------|-------|-----------|
| 150B        | 84.59      | 56.17        | 6.15                      | 23.36 | 59.57     |
| 56B         | 84.35      | 55.13        | 5.47                      | 22.98 | 51.89     |
| 6B          | 74.70      | 36.72        | 3.97                      | 17.81 | 30.24     |

Table 4: In-context learning performance of ALL with different size of the pretraining data. The dataset is randomly sampled from the original corpus.

result shows that in-context learning ability can be emerged by combining two corpora, even if each of both corpora cannot provide in-context learning ability. For example, KiN+Ency model succeeds to make in-context learning ability in most tasks, while each of KiN and Ency fails in most tasks. Likewise, Cafe+KiN model succeeds to make in-context learning ability, while each of Cafe and KiN fails in most tasks.

This phenomenon is related to the argument that in-context learning emerges by multi-task learning. According to the argument, as the language modeling objective function requires a language model to learn variety of next word prediction tasks, the generalization pushes in-context learning ability on unseen tasks. In the example of KiN+Ency model, KiN+Ency learns in-context learning ability of MRC task, by learning next word prediction tasks of both Ency (Wikipedia) and KiN (QnA).

Unlike these positive cases, we observe that combining corpora does not assure the emergence of competitive in-context learning from the case of Cafe+News. Even if the mixed corpus model shows slightly better performance on KorQuAD

than each of two corpora, its performances on NSMC, KorQuAD, and YNAT are still below the basis. Furthermore, the performances on NSMC and YNAT even decrease.

#### 4.4 Effect of Domain Relevance

Table 2 also shows that the close relationship between a pretraining corpus and a downstream task does not always guarantee in-context learning ability on the downstream task. KiN and Ency do not perform well on KorQuAD task, although KorQuAD is an MRC task from Korean Wikipedia, Ency includes Korean Wikipedia, and KiN consists of question answering pair, respectively. Likewise, News does not perform well on YNAT task, although YNAT consists of news headline queries. Table 3 further shows that News+KiN+Ency model shows more degenerated F1 score on YNAT than KiN+Ency, even though a large amount of News corpus is added to News+KiN+Ency model.

For further investigation, we analyze vocabulary statistics of each corpus. Figure 1 shows the vocabulary overlapping ratio between pretraining corpora and downstream tasks. The result shows that high vocabulary overlap between a pretraining corpus and a downstream task does not indicate high downstream task performance. Although the Modu corpus has a large vocabulary overlapping ratio to AI Hub, in-context learning performances of the Modu model on the translation task are much lower than Blog and KiN.

The counter example of above supports is AI

Figure 2: In-context learning performance of various corpus models and their PPL. A score of the model is divided by that of ALL to calculate the normalized performance. Blue and red lines denote the performance of ALL model and majority baseline, and the purple line represents the average of both defined in the caption of Table 3.

Hub task performance of KiN model. KiN model learned the pattern of Korean-English sentence pairs, since the corpus includes a lot of Korean questions on English language. While KiN model does not work well in other downstream tasks, the performance on AI Hub translation is competitive and makes the best performance in Ko→En among seven pretraining corpora.

We carefully conjecture that pretraining significantly improves in-context learning performance when both query and answer related to the downstream task exist in the pretraining corpus document. Additional analysis is required to clearly discover this hypothesis.

#### 4.5 Perplexity and Downstream Task

Figure 2 presents the scatter plots of PPL ( $x$ -axis) and in-context learning performance ( $y$ -axis) on five downstream tasks for single corpus models

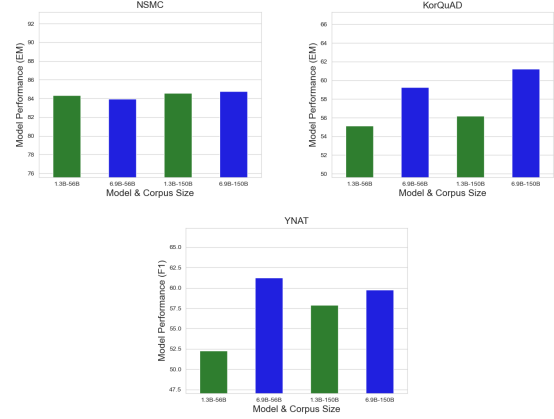

Figure 3: Comparison on two model sizes and two corpus sizes of the original HyperCLOVA corpus such as 1.3B-sized model and 6.9B-sized model, and 56B and 150B tokens. Green rectangle denotes 1.3B-sized model and blue rectangle denotes 6.9B-sized model.

and the ALL model. In Figure 2, we normalized in-context learning performance by dividing ALL model performance for calibrating various task metrics. Because we observe less explicit tendency of correlation between validation perplexity and in-context performance, we argue that it is difficult to hypothesize better perplexity assures emerging of in-context learning ability.

According Table 2, Blog model shows both lowest PPL and best in-context learning performance, and Ency model shows both highest PPL and worst in-context learning performance. On the contrary, while Cafe model and KiN model shows the second and third lowest PPL, in-context learning ability was not observed. These results show that perplexity does not serve as a strong predictor of in-context learning performance in comparing models trained using different corpora. Table 2 also shows that corpus size affects in-context learning performance more than PPL. Blog 27B performs quite worse than Blog, but PPL relatively does not decrease much.

Table 5 shows validation perplexity scores per each subcorpus. One row denotes the model and one column denotes the validation set’s subcorpus. Each validation set except All in Table 5 consists of 10,000 instances, and is the part of our main validation sets, consists of 70,000 instances. Figure 5 in Appendix A, supporting Table 5, also shows the validation perplexity of different models from different subcorpora.

On the other hand, Figure 4 shows that PPL and in-context learning performance correlate well

|          | Blog          | Cafe          | News         | Comments      | KiN           | Modu         | Ency          | All           |
|----------|---------------|---------------|--------------|---------------|---------------|--------------|---------------|---------------|
| Blog     | <i>126.89</i> | <b>201.15</b> | <b>83.98</b> | 599.68        | <b>138.95</b> | 98.83        | <b>108.17</b> | <b>152.40</b> |

| Ency     | 841.53        | 1348.38       | 213.87       | 5889.79       | 543.69        | 266.11       | <i>73.06</i>  | 549.40        |

Table 5: Validation perplexity scores per each subcorpus. All denotes the validation perplexity on our main validation set from seven corpus sources. *Italic* font denotes the validation PPL of their corpus domain, and **Bold** denotes second best after own corpus. Overall, `Blog` has the best overall validation perplexity in most tasks.

Figure 4: Relation between validation PPL and in-context learning performance for five downstream tasks as pretraining steps proceed.

when training a single model. We can find that the correlation trends between the cases in the training and the cases between the corpus domain are different.

## 5 Discussion

Our knowledge can be used in terms of increasing the performance of in-context learning where their corpus is small, and demand exists for collecting more corpus. In the case of XGLM (Lin et al., 2021), which is a concurrent work on multilingual GPT-3, achieved better in-context learning performance for many languages. However, it does not reach the performance of a single language model. We hope our observation can give insight into what types of pretraining to be collected more, both for multilingual model and low-resource lan-

guage model.

Another notable example comes from Gopher (Rae et al., 2021), which is a concurrent work on state-of-the-art in-context learner. Rae et al. (2021) determine the ratio between subcorpora based on the perplexity of the validation corpus. They implicitly claim that this ratio results in better downstream task performance, but do not address explicit evidence for this. On the other hand, we are in a position to doubt the strong correlation between perplexity and in-context learning. We hope our findings contribute to making better in-context learners along with other research.

## 6 Conclusion

This paper investigates the effects of the source and the size of the training corpus on in-context learning ability, using the HyperCLOVA corpus. Our discoveries include that corpus sources play a crucial role in whether or not in-context learning ability will emerge in a large-scale language model. Interestingly, in-context learning ability emerges when a model was trained with the two corpora that do not incur in-context learning ability when used alone. In addition, our analyses reveal that larger pretraining data and vocabulary overlapping between a pretraining corpus and a downstream corpus do not always lead to a better in-context language model.

One direction for future work is to investigate linguistic properties of corpus sources which make a competitive in-context learning model. For example, quantifying the difference between two corpora can shed light on how to select suitable corpora for NLP practitioners who build large-scale language models. In addition, intensive studies on different corpus sources other than the HyperCLOVA corpus can help understand the properties of in-context learning.

## Broader Impact Statement

We present multiple pieces of evidence that models using only a part of the pretraining corpus are comparable with those trained with the entire corpus in terms of in-context performances. Although we leave the validation on larger-scale models, such as tens of billion parameters, to future work, our analysis presents a hint to effectively training LMs with smaller corpora. This approach can contribute to alleviating severe energy consumption issues caused by large-scale LMs.

Meanwhile, our study relates to the misuse and fairness of large-scale LMs. For example, reweighting domain-specific corpus might cause LMs to be biased inherent in the domain corpus. Therefore, alleviating domain corpus bias would be a valuable future direction.

## A Details on Experimental Results

Table 6 shows score difference with ALL in addition to in-context learning scores on Table 2. Figure 5 shows the validation perplexity of different model from different corpus.

## B Details on Pretraining Corpus

Tables 7 and 8 show example instances of seven pretraining corpus in Korean and English, respectively.

For preprocessing steps of our pretraining corpus, we use HyperCLOVA corpus which is also used in (Kim et al., 2021) as described in Section 3.1. Therefore, we share the preprocessing steps of Kim et al. (2021). Appendix A in (Kim et al., 2021) describes their preprocessing methods on data descriptoin, data clearing, data anonymization, and data postprocessing.

### B.1 Deduplication Preprocess

We additionally introduce the deduplication preprocess of HyperCLOVA corpus, which is used in (Kim et al., 2021). The deduplication preprocess was applied to construct HyperCLOVA corpus to prevent explicit duplication within and between subcorpora (Kim et al., 2021). According to the response of Kim et al. (2021), they use an in-house search engine and an in-house engineering trick to detect document pairs that are very similar to each other. There are two pipelined steps: (1) removing duplicates within subparts of the corpus, and then (2) removing duplicates between subparts of the corpus. Therefore, documents with high overlap do not exist throughout the documents. Here, the

number of subparts is 29. These 29 subparts are categorized into the eight domains we deal with in the paper (i.e., Blog, News, Cafe, Comments, KiN, Modu, Ency, and Others). Overall, there is no explicit overlap between each corpus, since very similar documents have already been removed from the corpus. The overlap between eight HyperCLOVA subcorpora is quite small. There were many overlaps within the subpart of the corpus. However, the overlap between subparts of the corpus was only 0.024% of the total, according to the counts in the second pipelined step of deduplication between subparts.

## C Examples of Few-shot Prompt

Tables 9, 11, 13, and 14 show the example few-shot prompt of NSMC, KorQuAD, AI Hub, and YNAT, respectively. Tables 10, 12, and 15 show the translated version for NSMC, KorQuAD, and YNAT, respectively.

On the other hand, the number of random seed is one for KorQuAD. We explain why evaluation on KorQuAD with many random seeds is difficult, from the perspective of prompt design. The way we make randomness on trials to change few-shot examples. However, in the case of Kim et al. (2021) and in our case, there are no alternative examples to put into the prompt. The prompt examples of KorQuAD are one document and a few question-answer pairs, and not a few document-question-answer triples. In other words, in the prompt of KorQuAD, the number of the document is one. Thus, the document is used for both few-shot question-answer pairs and a query question for the inference. In KorQuAD, there are five corresponding question-answer pairs in each document. In the experimental setting of ours and Kim et al. (2021), four question-answers are put into the prompt and one question is used for the test. Therefore, there are no other question-answer pairs to replace the four pairs.

## D Generalization to Other Languages

Someone can ask whether our results can be extended to other language, including English. We have left experiments on non-Korean language as future work. However, we describe some explanations below to defend our experiments on the Korean language and to discuss why experiments on other languages are practically non-trivial.

First, we think our findings are basically generalizable to other languages. From the perspective

| Corpus Type   | Corpus Train | NSMC (Acc)           | KorQuAD (EM) (F1)    |                      | AI Hub (BLEU) Ko→En En→Ko |                     | YNAT (F1)            |

Table 6: Table 3 which includes the difference from ALL in parentheses.

of pretraining and in-context learning, fundamental differences between Korean and English were limitedly reported. For example, XGLM (Lin et al., 2021), a concurrent work on, also does not show critical evidence on language-specific properties.

Second, It is non-trivial to control various aspects of corpora for our purpose. Most corpus for in-context few-shot learners comes from crawled web site which is not easy to distinguish from its original source. For example, 82% of OpenAI GPT-3 Corpus (Brown et al., 2020) is a filtered version of Common Crawl. In this regard, we used relatively a well-refined corpus which consist of several subcorpus from a single web service. (Please see also Section B.1 of this letter.) On the other hand, we have interests to extend our work onto Pile dataset (Gao et al., 2020), by controlling the subcorpora in the direction our study pursuits, in the future.

| News     | <p>News</p> <p>Title: Jeon Myeonghwan and Lee Byungki won the Poem Literature Award.</p> <p>Body: The winners of the 2016 Young Poetry Literature Award and Choi Myung-hee Young Novel Literature Award have been decided. While the awards ceremony was held at Jeonbuk National University's president's office on the 1st, Jeon Myung-hwan (second year of Chung-Ang University's Korean Language Language) who wrote "the past" in the college category and Hwang Joo-yeon (second year of Gyeongsan Girls' High School) were selected. Yoon Sun-mi (3rd year of Moonchang, Seoul Digital University), who wrote "From Flowers" in the college category of Choi Myung-hee's Youth Novel Literature Award, and Yoon Jung-eun (2nd year of Anyang Arts High School), who wrote "Night Flight" in the high school category, were honored. The contest, co-hosted by Jeonbuk National University (President Lee Nam-ho) newspaper broadcasters, Honbul Memorial Society, and Choi Myung-hee Literature Museum (CEO Jang Sung-soo), featured 669 works of 167 people in the poetry category and 116 works of 108 people in the novel category this year. Choi Seung-beom, Yang Byung-ho, Yoo Seung-chul, a member of the Yoo In, and Seo Cheol-won, Hwang Bo-yoon, Jang Mari, Kim So-yoon, and Choi Ki-woo, a member of the novel division, were in charge of the screening. Park Joon-ho, chairman of the Literature Award's steering committee and weekly newspaper broadcaster, commented, "It was high-quality, and I could get a glimpse of the difficult worries and thoughts of young people looking at the times."</p> |
| Comments | <p>Conversation</p> <p>Body: You spend a long day.^^ Eat more for lunch.</p> <p>It's brunch. We have to wait for dinner.^^</p> <p>What kind of exercise do you do after eating like this? Don't do sit-ups in the evening.</p> <p>I've been skipping it from time to time. I'm going to visit Anderson next Monday and Tuesday.Let's go together, right?</p> <p>Next Monday and Tuesday?^^ I have to go, I'm going...I'll make time to go there.^^ How are you going to move?</p> <p>On Tuesday... I have to take the subway, so where will you leave?</p> <p>I'm departing from Seongsu-dong, Seoul. If you come all the way to Seongsu, I'll take you.^^</p>  |
| KiN      | <p>QnA</p> <p>Question: Doksilagae? It's a dialect. What does doksilagae mean? It's used near Gyeongsang-do.</p> <p>Text: In Gyeongsang-do dialect, it means tremendously.It's an adverb to emphasize.</p>  |
| Modu     | <p>News</p> <p>Text: It snowed in the spring equinox in Busan...Strong winds are blowing and they're avoiding it. Yonhap News Agency reported that 0.7 centimeters of snow fell on the 21st, the spring equinox in Busan, where snow was not easy, and roads in mountainous areas were controlled. According to the Busan Meteorological Administration, the lowest temperature in the morning in Busan was 1 degree in Daecheong-dong, Jung-gu, where the official observation station is located. Seodaemun-dong, Jung-gu, with an altitude of more than 500m above sea level, recorded minus 1.4 degrees Celsius and Yeongdo-gu recorded minus 0.9 degrees Celsius. As strong winds blew, the sensible temperature dropped to minus 2.6 degrees Celsius. As the morning low temperature crossed below zero, the rain that had been falling all night turned into sleet. The automatic snow observation equipment of the Korea Meteorological Administration in Gijang-gun, Busan recorded a snowfall of 0.7cm. As snow piled up on mountain roads in Buk-gu, Sasang-gu, and Gijang-gun, eight vehicles, including Gomnaejae Pass, Igok Pass, Geumjeong-gu Sanseong-ro, Mandeok Pass Road in Buk-gu, and Hwangnyeongsan-ro in Yeonje-gu, were once controlled in the morning. Local governments and others in charge carried out snow removal work by mobilizing working vehicles to spray calcium chloride.</p>  |
| Ency     | <p>Document</p> <p>Title: Seorakmyeon.</p> <p>Body: Seorak-myeon is a myeon of Gapyeong-gun, Gyeonggi-do, Korea. The area is 141.53 km<sup>2</sup>, and the population is 8,986 based on resident registration at the end of December 2016. Seorak-myeon was originally part of Yangpyeong-gun in the south of the Bukhangang River, but was incorporated into Gapyeong-gun in 1942. It has nothing to do with Seoraksan Mountain in Gangwon-do.</p>  |

| Context ->           | <p>Title: Lim Jongseok.</p> <p>Main Text: On February 15, 1989, he was wanted for leading a violent demonstration against farmers in Yeouido (violence of the Punishment of Violence, etc. Act). On March 12, 1989, the Ministry of Public Security of the Seoul District Prosecutors' Office received a preliminary arrest warrant for Lim Jong-seok. On June 30 of the same year, Lim Soo-kyung was dispatched as a representative to the Pyongyang Festival, adding charges of violating the National Security Act. The police obtained information that Lim Jong-seok was pushing for a statement at Kyung Hee University in Seoul between December 18 and December 18, and distributed 22 plainclothes police, including 12 special forces and anti-aircraft staff armed with gas guns and electronic rods, to Kyung Hee University. At around 8:15 a.m. on December 18, 1989, the Seoul Cheongnyangni Police Station found Lim Jong-seok, who came down the stairs of the Kyunghee University Student Center building with five escort students, arrested him and executed his arrest. Lim Jong-seok was investigated by the Cheongnyangni Police Station for about an hour and handed over to the Seoul Metropolitan Police Agency's public security loss office in Jangan-dong, Seoul, at around 9:50 a.m.</p> <p>Question: Who was dispatched as a representative at the Pyongyang Festival on June 30, 1989?</p> <p>Answer : Lim Su-kyung</p> <p>Question: When was Lim Jong-seok wanted to be arrested for leading a violent demonstration against farmers in Yeouido?</p> <p>Answer: 1989</p> <p>Question: Where in Kyung Hee University did you arrest Lim Jong-seok?</p> <p>Answer: Stairs in the building of the student center.</p> <p>Question: Where was Lim Jongseok handed over after being investigated?</p> <p>Answer: Seoul Metropolitan Police Agency lost public security.</p> <p>Question: What is the name of the person who was wanted for leading the Yeouido peasant violence protest on February 15, 1989?</p> <p>Answer:</p> |
| Target Completion -> | Lim Jongseok.  |
